## Exercise Sheet 11

## Exercise 1: Designing a Neural Network (30 P)

We would like to implement a neural network that classifies data points in  $\mathbb{R}^2$  according to decision boundary given in Figure 1 (see below). We consider as an elementary computation the *threshold neuron* whose relation between inputs  $(a_i)_i$  and output  $a_j$  is given by

$$z_j = \sum_i a_i w_{ij} + b_j \qquad a_j = 1_{z_j > 0}.$$

(a) Design at hand a neural network that takes  $x_1$  and  $x_2$  as input and produces the output "1" if the input belongs to class A, and "0" if the input belongs to class B. Draw the neural network model and  $write\ down$  its corresponding weight and bias parameters.

## Exercise 2: Backward Propagation (40 P)

We consider a neural network with the structure given in Figure 2 (see below). For simplicity, we consider biases to be zero. The elementary computation of this network is the *sigmoid neuron* defined as:

$$z_j = \sum_i a_i w_{ij} \qquad \qquad a_j = \frac{e^{z_j}}{1 + e^{z_j}}$$

For example, when applied to the neuron 7, it can be written explicitely as:

$$z_7 = x_3 \cdot w_{37} + a_5 \cdot w_{57} \qquad \qquad a_7 = \frac{e^{z_7}}{1 + e^{z_7}}$$

The error function is the squared norm between a target vector  $\mathbf{t} = (t_8, t_9)$  and the vector of output activations  $\mathbf{f}(\mathbf{x}, \mathbf{w}) = (a_8, a_9)$ . That is, the error for a given labeled data point  $(\mathbf{x}, \mathbf{t})$  can be expressed as a function of the parameter vector  $\mathbf{w} = (w_{14}, w_{16}, w_{26}, \dots)$  as:

$$E(\boldsymbol{w}) = \|\boldsymbol{y}(\boldsymbol{x}, \boldsymbol{w}) - \boldsymbol{t}\|^2.$$

(a) Write the sequence of computations that leads to the evaluation of the error partial derivatives  $\partial E/\partial w_{14}$  and  $\partial E/\partial w_{16}$ . Your answer should outline which computations are common to these two evaluations. Also note that the derivative of the sigmoid activation function can be expressed in terms of neuron activations themselves as  $\partial a_j/\partial z_j = a_j \cdot (1 - a_j)$ .

## Exercise 3: Optimization (30 P)

Consider a simple neural network composed of two neurons with linear activation functions. It is described by the equations

$$z_2 = x_1 w_{12}$$
  $a_2 = z_2$   
 $z_3 = a_2 w_{23}$   $a_3 = z_3$ 

with one-dimensional input  $x = x_1$ , and one-dimensional output  $f(x) = a_3$ , and where  $w_{12}$  and  $w_{23}$  are the parameters to learn. We consider the labeled dataset consisting of three data points:  $(x^{(1)}, t^{(1)}) = (-1, -1), (x^{(2)}, t^{(2)}) = (0, 0),$  and  $(x^{(3)}, t^{(3)}) = (1, 1)$ . We would like to minimize the error  $E(w_{12}, w_{23}) = \sum_{n=1}^{3} (f(x^{(n)}) - t^{(n)})^2$ .

- (a) Analyze the error function at  $(w_{12}, w_{23}) = (0, 0)$ , and explain what would be the outcome of starting gradient descent at this point in the parameter space.
- (b) Show that there are an infinite number of solutions with error  $E(w_{12}, w_{23}) = 0$ .
